STUDENT DROPOUT PREDICTION

PROGRAM

```
import pandas as pd
from sklearn.linear_model import LogisticRegression

# Create student dataset
data = {
    'Attendance': [90, 85, 80, 75, 70, 65, 60, 55, 50, 45],
    'Marks': [90, 85, 80, 75, 70, 65, 60, 50, 45, 40],
    'Assignments': [10, 9, 9, 8, 7, 6, 6, 5, 4, 3],
    'Dropout': [0, 0, 0, 0, 0, 0, 1, 1, 1, 1]
}

df = pd.DataFrame(data)

# Input features and target
X = df[['Attendance', 'Marks', 'Assignments']]
y = df['Dropout']

# Train the model
model = LogisticRegression()
model.fit(X, y)

# Get student details
attendance = float(input("Enter attendance percentage: "))
marks = float(input("Enter marks: "))
assignments = int(input("Enter completed assignments: "))

# Predict dropout status
prediction = model.predict([[attendance, marks, assignments]])

# Display result
if prediction[0] == 1:
    print("Prediction: Student is at risk of dropping out.")
else:
    print("Prediction: Student is likely to continue education.")
```

OUTPUT (Sample)

```
Enter attendance percentage: 40
Enter marks: 35
Enter completed assignments: 2

Prediction: Student is at risk of dropping out.
```

Note: This is a sample output from the demonstration dataset. The prediction may vary depending on input values and model behavior.
